### A word about UPMC and ISIR

### Université Pierre et Marie Curie

• A "Science" University :

From Astrophysics to Zoology...

• Around 38000 students and 120 research laboratories.

### A word about UPMC and ISIR

### Université Pierre et Marie Curie

• A "Science" University :

From Astrophysics to Zoology...

• Around 38000 students and 120 research laboratories.

### Institut des Systèmes Intelligents et de Robotique

- A "young" lab. born from the fusion of three different labs in jan. 2007.
- 100 people among which 30 faculties.
- Lab. director : Prof. Philippe Bidaud.
- 3 research groups :
  - Interactive Systems : micro/nano-manipulation, surgical robotics
  - Mobile and autonomous Systems : bio-inspired robotics, mobile robotics, autonomous systems
  - Perception and Motion : Human and artificial perception, motion analysis, rehabilitation, humanoid robots control

- 1 How are robots controlled (in 1 slide)?
- 2 How should we control robots (in 1 slide)?
- 3 What is nice about model-based control?
- Why does learning has to be included?
- 5 Locally Weighted Projection Regression
- Our approach to combine OSC and learning
- Some results in simulation and using a toy-like robot

## How are robots controlled (in 1 slide)? ... And what's the impact on safety?

## How are robots controlled (in 1 slide)? ... And what's the impact on safety?

### Stiff PID control

- Inherited from industrial Robotics tasks : repeatability
- Not much model needed
- Usually : stiff actuators, high embedded inertias, no natural back-drivability
  This is obviously dangerous if Humans are in the robots' environment.

### How are robots controlled (in 1 slide)? ... And what's the impact on safety?

### Stiff PID control

- Inherited from industrial Robotics tasks : repeatability
- Not much model needed
- Usually : stiff actuators, high embedded inertias, no natural back-drivability This is obviously dangerous if Humans are in the robots' environment.

#### Model-based control

- Provides a sound framework to the control problem
- Allows to generate controlled compliance
- Requires a good knowledge of the systems dynamics
  Ultimately, if the control fails, the actuation type and inertias localization will condition the robot's dangerousness

### How are robots controlled (in 1 slide)? ... And what's the impact on safety?

### Stiff PID control

- Inherited from industrial Robotics tasks : repeatability
- Not much model needed
- Usually : stiff actuators, high embedded inertias, no natural back-drivability This is obviously dangerous if Humans are in the robots' environment.

#### Model-based control

- Provides a sound framework to the control problem
- Allows to generate controlled compliance
- Requires a good knowledge of the systems dynamics
  Ultimately, if the control fails, the actuation type and inertias localization will condition the robot's dangerousness

#### Model free, learning-based (NN, RL) control

- No a priori knowledge required, on-line adaptation
- Stability of the resulting controllers is hard to prove
- Deriving a generic control method is not easy ⇒ Same conclusion !

## How should we control robots (in 1 slide)?

It depends...

Within the framework of personal Robotics applications :

### How should we control robots (in 1 slide)?

It depends...

Within the framework of personal Robotics applications :

- The environment is not structured and dynamically evolving
- Humans are moving around
- Tasks are highly complex and of very different natures

### How should we control robots (in 1 slide)?

It depends...

Within the framework of personal Robotics applications :

- The environment is not structured and dynamically evolving
- Humans are moving around
- Tasks are highly complex and of very different natures

So we need : aware (perceptive), adaptive, safe, and versatile robots.

### How should we control robots (in 1 slide)?

It depends...

Within the framework of personal Robotics applications :

- The environment is not structured and dynamically evolving
- Humans are moving around
- Tasks are highly complex and of very different natures

So we need : aware (perceptive), adaptive, safe, and versatile robots.

#### First steps...

- Equip our robots with a redundant number of sensors and actuators (humanoids?)
- Stop actuating robots with DC motors and high gear ratios.
- Use the nice framework offered by model-based control.
- Don't trust models and put some learning in the loop.

### What is nice about model-based control?

Well, let's focus : What is nice about operational space control ?

It relates the task space (what I want to control) to the joints space (what I can actually control)

- At the geometric level :  $\mathbf{x} = h(\mathbf{q}) \rightarrow \text{non-linear}$  : too complex
- At the kinematic level :  $\dot{\mathbf{x}} = J(\mathbf{q})\dot{\mathbf{q}}$
- At the dynamic level :  $\mathbf{\Gamma} = M(\mathbf{q})\ddot{\mathbf{q}} + C(\mathbf{q},\dot{\mathbf{q}})\dot{\mathbf{q}} + \mathbf{g}(\mathbf{q}) + \mathbf{\Gamma}_{ext}$
- In a combined fashion :  $\mathbf{f} = \Lambda(\mathbf{q})\ddot{\mathbf{x}} + \mu(\mathbf{q},\dot{\mathbf{q}}) + \mathbf{p}(\mathbf{q}) + \mathbf{f}_{ext}$

## Locally Weighted Projection Regression

- T

Why learning?

LWPR OSC + learning Results

LWPR is a function approximator which provides accurate approximation in very large spaces in a O(n) complexity, where n is the number of sample data.

### Locally Weighted Projection Regression

LWPR is a function approximator which provides accurate approximation in very large spaces in a O(n) complexity, where n is the number of sample data.

- Uses a combination of linear models (called Receptive Fields (RFs)) (RLS)
- Each model is valid on an elliptic zone of the inputs space
- The prediction made by LWPR for a given input vector is a weighted sum of the results of all the active surroundings RFs.
- RFs are created and destroyed incrementally
- Only relevant combination of the input vector are kept in the learnt model (PLS)

Some possible extensions

イロト イロト イヨト イヨト

Ξ.

#### Some possible extensions

Bernstein in 1967 raised the following paradox : thanks to the redundancy of their motor system, human beings can realize a task from an infinity of ways. However, for a given task, they always reproduce the same kind of stereotypic motion. The problem consists in explaining where these regularities come from, given the diversity of possible solutions.

#### Some possible extensions

Bernstein in 1967 raised the following paradox : thanks to the redundancy of their motor system, human beings can realize a task from an infinity of ways. However, for a given task, they always reproduce the same kind of stereotypic motion. The problem consists in explaining where these regularities come from, given the diversity of possible solutions.

Can we get an idea of what is the optimal motion criteria using motion capture data and learnt direct and inverse models? This vision of human motion is a bit simplistic. But we may try !
