Main Aim

Production of energy by means of a fusion reaction

Plasma

- ▶ High temperature and pressure are needed
- ▶ Fully ionised gas \mapsto Plasma
- ▶ Magnetic field is needed to confine the plasma

- ▶ In tokamaks, **magnetic control of the plasma is obtained by means of magnetic fields produced by the external active coils**
- ▶ In order to obtain good performance, it is necessary to have a plasma with **vertically elongated cross section** \Rightarrow **vertically unstable plasmas**
- ▶ It is important to **maintain adequate plasma-wall clearance during operation**

References

1. The plasma/circuits system is axisymmetric
2. The inertial effects can be neglected at the time scale of interest, since plasma mass density is low
3. The magnetic permeability μ is homogeneous, and equal to μ_0 everywhere

Mass vs Massless plasma

It has been proven that neglecting plasma mass may lead to erroneous conclusion on closed-loop stability.

Different model outputs can be chosen:

- ▶ fluxes and fields where the magnetic sensors are located
- ▶ currents in the active and passive circuits
- ▶ plasma radial and vertical position (1st and 2nd moment of the plasma current density)
- ▶ geometrical descriptors describing the plasma shape (gaps, x-point and strike points positions)

By using finite-elements methods, **nonlinear** lumped parameters approximation of the PDEs model is obtained

$$\frac{d}{dt} [\mathcal{M}(\mathbf{y}(t), \beta_p(t), l_i(t)) \mathbf{I}(t)] + \mathbf{R} \mathbf{I}(t) = \mathbf{U}(t),$$
$$\mathbf{y}(t) = \mathcal{Y}(\mathbf{I}(t), \beta_p(t), l_i(t)).$$

where:

- ▶ $\mathbf{y}(t)$ are the output to be controlled
- ▶ $\mathbf{I}(t) = [\mathbf{I}_{PF}^T(t) \mathbf{I}_e^T(t) I_p(t)]^T$ is the currents vector, which includes the currents in the active coils $\mathbf{I}_{PF}(t)$, the eddy currents in the passive structures $\mathbf{I}_e(t)$, and the plasma current $I_p(t)$
- ▶ $\mathbf{U}(t) = [\mathbf{U}_{PF}^T(t) \mathbf{0}^T 0]^T$ is the input voltages vector
- ▶ $\mathcal{M}(\cdot)$ is the mutual inductance nonlinear function
- ▶ \mathbf{R} is the resistance matrix
- ▶ $\mathcal{Y}(\cdot)$ is the output nonlinear function

Starting from the nonlinear lumped parameters model, the following plasma linearized state space model can be easily obtained:

$$\delta\dot{\mathbf{x}}(t) = \mathbf{A}\delta\mathbf{x}(t) + \mathbf{B}\delta\mathbf{u}(t) + \mathbf{E}\delta\dot{\mathbf{w}}(t), \quad (1)$$

$$\delta\mathbf{y}(t) = \mathbf{C}\delta\mathbf{l}_{PF}(t) + \mathbf{F}\delta\mathbf{w}(t), \quad (2)$$

where:

- ▶ **A**, **B**, **E**, **C** and **F** are the model matrices
- ▶ $\delta\mathbf{x}(t) = [\delta\mathbf{l}_{PF}^T(t) \delta\mathbf{l}_e^T(t) \delta l_p(t)]^T$ is the state space vector
- ▶ $\delta\mathbf{u}(t) = [\delta\mathbf{U}_{PF}^T(t) \mathbf{0}^T 0]^T$ are the input voltages variations
- ▶ $\delta\mathbf{w}(t) = [\delta\beta_p(t) \delta l_i(t)]^T$ are the β_p and l_i variations
- ▶ $\delta\mathbf{y}(t)$ are the output variations

The model (1)–(2) relates the variations of the PF currents to the variations of the outputs around a given equilibrium

A **linear time-invariant (LTI)** continuous-time system is described by

$$\dot{x}(t) = Ax(t) + Bu(t), \quad x(0) = x_0 \quad (3a)$$

$$y(t) = Cx(t) + Du(t) \quad (3b)$$

where $A \in \mathbb{R}^{n \times n}$, $B \in \mathbb{R}^{n \times m}$, $C \in \mathbb{R}^{p \times n}$ and $D \in \mathbb{R}^{p \times m}$.

A dynamical system with single-input ($m = 1$) and single-output ($p = 1$) is called **SISO**, otherwise it is called **MIMO**.

Asymptotic stability

This property roughly asserts that every solution of $\dot{x}(t) = Ax(t)$ tends to zero as $t \rightarrow \infty$.

For LTI systems the stability property is related to the system and not to a specific equilibrium

Theorem - System (3) is **asymptotically stable** iff A is Hurwitz, that is if every eigenvalue λ_j of A has strictly negative real part

$$\Re(\lambda_j) < 0, \forall \lambda_j.$$

Theorem - System (3) is **unstable** if A has at least one eigenvalue $\bar{\lambda}$ with strictly positive real part, that is

$$\exists \bar{\lambda} \text{ s.t. } \Re(\bar{\lambda}) > 0.$$

Theorem - Suppose that A has all eigenvalues λ_j such that $\Re(\lambda_j) \leq 0$, then system (3) is **unstable** if there is at least one eigenvalue $\bar{\lambda}$ such that $\Re(\bar{\lambda}) = 0$ which corresponds to a Jordan block with size > 1 .

Given a LTI system (3) the corresponding *transfer matrix* from u to y is defined as

$$Y(s) = G(s)U(s),$$

with $s \in \mathbb{C}$. $U(s)$ and $Y(s)$ are the Laplace transforms of $u(t)$ and $y(t)$ with zero initial condition ($x(0) = 0$), and

$$G(s) = C(sI - A)^{-1}B + D. \quad (4)$$

For SISO system (4) is called *transfer function* and it is equal to the Laplace transform of the **impulsive response** of system (3) with zero initial condition.

Given the transfer function $G(s)$ and the Laplace transform of the input $U(s)$ the time response of the system can be computed as the inverse transform of $G(s)U(s)$, **without solving differential equations**

As an example, the **step response** of a system can be computed as:

$$y(t) = \mathcal{L}^{-1} \left[G(s) \frac{1}{s} \right].$$

Given a SISO LTI system, its transfer function is a rational function of s

$$G(s) = \frac{N(s)}{D(s)} = \rho \frac{\prod_i (s - z_i)}{\prod_j (s - p_j)},$$

where $N(s)$ and $D(s)$ are polynomial in s , with $\deg(N(s)) \leq \deg(D(s))$.

We call

- ▶ p_j **poles** of $G(s)$
- ▶ z_i **zeros** of $G(s)$

Every pole of $G(s)$ is an eigenvalue of the system matrix A . However, not every eigenvalue of A is a pole of $G(s)$

The plasma (axisymmetric) magnetic control in tokamaks includes the following three control problems

- ▶ the vertical stabilization problem
- ▶ the shape and position control problem
- ▶ the plasma current control problem

Objectives

- ▶ Vertically stabilize elongated plasmas in order to avoid disruptions
- ▶ Counteract the effect of disturbances (ELMs, fast disturbances modelled as VDEs, . . .)
- ▶ **It does not necessarily control vertical position but it *simply* stabilizes the plasma**
- ▶ **The VS is the essential magnetic control system!**

Simplified filamentary model

Consider the simplified electromechanical model with three conductive rings, two rings are kept fixed and in symmetric position with respect to the r axis, while the third can freely move vertically.

If the currents in the two fixed rings are equal, the vertical position $z = 0$ is an equilibrium point for the system.

Motivation

- ▶ Plasma magnetic control is one of the the crucial issue to be addressed
 - ▶ **is needed from day 1**
 - ▶ **is needed to robustly control elongated plasmas** in high performance scenarios

A proposal for magnetic control in ITER & DEMO (and more)

- ▶ A magnetic control system able to operate the plasma for an entire duration of the discharge, from the initiation to plasma ramp-down
- ▶ *Machine-agnostic* architecture (aka *machine independent* solution)
- ▶ Model-based control algorithms
 - ▶ → the design procedures relies on (validated) control-oriented models for the response of the plasma and of the surrounding conductive structures
- ▶ The proposal is based on the JET experience
- ▶ The architecture has been proposed for ITER & DEMO (& JT-60SA) and partially deployed at EAST

- ▶ Let g_i be the abscissa along i -th control segment ($g_i = 0$ at the first wall)
- ▶ Plasma shape control is achieved by imposing

$$g_{i_{ref}} - g_i = 0$$

on a sufficiently large number of control segments (**gap control**)

- ▶ Moreover, if the plasma shape intersect the i -th control segment at g_i , the following equation is satisfied

$$\psi(g_i) = \psi_B$$

where ψ_B is the flux at the plasma boundary

- ▶ Shape control can be achieved also by controlling to 0 the (**isoflux control**)

$$\psi(g_{i_{ref}}) - \psi_B = 0$$

- ▶ $\psi_B = \psi_X$ for *limited-to-diverted* transition
- ▶ $\psi_B = \psi_L$ for *diverted-to-limited* transition

Figure: Control segments.

References

- ▶ The XSC-like plasma shape controller can be applied both adopting a **isoflux** or a **gap** approach
- ▶ It relies on the current PF current controller which achieves a **good decoupling** of the PF circuits
 - ▶ Each PF circuits can be treated as an independent SISO channel

$$I_{PF_i}(s) = \frac{I_{PF_{ref},i}(s)}{1 + sT_{PF}}$$

- ▶ If $\delta Y(s)$ are the variations of the n_G shape descriptors (e.g. fluxes differences, position of the x-point, gaps) – with $n_G \geq n_{PF}$ – then **dynamically**

$$\delta Y(s) = C \frac{I_{PF_{ref}}(s)}{1 + sT_{PF}}$$

and **statically**

$$\delta Y(s) = C I_{PF_{ref}}(s)$$

- ▶ The currents needed to track the desired shape (in a *least-mean-square* sense)

$$\delta I_{PF_{ref}} = C^\dagger \delta Y$$

- ▶ It is possible to use weights both for the shape descriptors and for the currents in the PF circuits
- ▶ The controller gains can be computed using the SVD of the weighted output matrix:

$$\tilde{C} = QCR = USV^T$$

- ▶ The XSC minimizes the cost function

$$\tilde{J}_1 = \lim_{t \rightarrow +\infty} (\delta Y_{ref} - \delta Y(t))^T Q^T Q (\delta Y_{ref} - \delta Y(t)),$$

using $n_{dof} < n_{PF}$ degrees of freedom, while the remaining $n_{PF} - n_{dof}$ degrees of freedom are exploited to minimize

$$\tilde{J}_2 = \lim_{t \rightarrow +\infty} \delta I_{PF_N}(t)^T R^T R \delta I_{PF_N}(t).$$

(it contributes to avoid PF current saturations)

Plant model (plasma and PF current controller)

The plant behavior around a given equilibrium is described by means of a linearized model

$$\dot{x} = Ax + Bu + B_d d, \quad (5a)$$

$$y = Cx + Du + D_d d, \quad (5b)$$

- ▶ $u \in \mathbb{R}^{n_{PF}}$ is the control input vector which holds the $n_{PF} = 8$ currents flowing in the PF coils devoted to the plasma shape control
- ▶ $y \in \mathbb{R}^{n_{SH}}$ is the controlled outputs vector which holds the n_{SH} plasma shape descriptors controlled by the XSC (typically, at JET, it is $n_{SH} = 32$)

The controller model (XSC controller)

The XSC can also be modeled as a linear time-invariant system

$$\dot{x}_C = A_C x_C + B_C u_C + B_r r, \quad (6a)$$

$$y_C = C_C x_C + D_C u_C + D_r r, \quad (6b)$$

under the interconnection conditions:

$$u_C = y, \quad (7a)$$

$$u = y_C. \quad (7b)$$

The current allocator

The allocator equations are given by

$$\dot{x}_a = -KB_0^T \begin{bmatrix} I \\ P^* \end{bmatrix}^T (\nabla J)^T \Big|_{(u, \delta y)}, \quad (8a)$$

$$\delta u = B_0 x_a, \quad (8b)$$

$$\delta y = P^* B_0 x_a. \quad (8c)$$

- ▶ $K \in \mathbb{R}^{n_a \times n_a}$ is a symmetric positive definite matrix used to specify the allocator convergence speed, and to distribute the allocation effort in the different directions
- ▶ $J(u^*, \delta y^*)$ is a continuously differentiable cost function that measures the trade-off between the current saturations and the control error (on the plasma shape)
- ▶ $B_0 \in \mathbb{R}^{n_{PF} \times n_a}$ is a suitable full column rank matrix,

When designing the current allocator, **a large number of parameters must be specified** by the user once the reference plasma equilibrium has been chosen:

- ▶ the two matrices P^* and B_0 , which are strictly related to the linearized plasma model (5)
- ▶ the K matrix
- ▶ the gradient of the cost function J must be specified by the user. In particular, the gradient of J on each *channel* is assumed to be piecewise linear

Figure: Piecewise linear function used to specify the gradient of the cost function J for each *allocated* channel. For each channel 7 parameters must be specified.

The CLA block is inserted between the *XSC* and the *Current Decoupling Controller*
