3. Zur Elektrodynamik bewegter Körper; von A. Einstein.

Daß die Elektrodynamik Maxwells - wie dieselbe gegenwärtig aufgefaßt zu werden pflegt - in ihrer Anwendung auf bewegte Körper zu Asymmetrien führt, welche den Phänomenen nicht anzuhaften scheinen, ist bekannt. Man denke z. B. an die elektrodynamische Wechselwirkung zwischen einem Magneten und einem Leiter. Das beobachtbare Phänomen hängt hier nur ab von der Relativbewegung von Leiter und Magnet, während nach der üblichen Auffassung die beiden Fälle, daß der eine oder der andere dieser Körper der bewegte sei, streng voneinander zu trennen sind. Bewegt sich nämlich der Magnet und ruht der Leiter, so entsteht in der Umgebung des Magneten ein elektrisches Feld von gewissem Energiewerte, welches an den Orten, wo sich Teile des Leiters befinden, einen Strom erzeugt. Ruht aber der Magnet und bewegt sich der Leiter, so entsteht in der Umgebung des Magneten kein elektrisches Feld, dagegen im Leiter eine elektromotorische Kraft, welcher an sich keine Energie entspricht, die aber - Gleichheit der Relativbewegung bei den beiden ins Auge gefaßten Fällen voransgesetzt - zu elektrischen Strömen von derselben Größe und demselben Verlaufe Veranlassung gibt, wie im ersten Falle die elektrischen Kräfte.

Beispiele khnlicher Art, sowie die millungenen Versucha; eine Bewegung die Feder valur zum "Lichtmediumi" m konstatieren; führen zu der Vernutung, daß dem Begriffe der sohnten Rube nicht nur in der Mechanit, sondern auch in der Elektrodynamik keine Eigenschaften der Erscheinungen entgeichen einder als vielnehrt für alle Koordinatonystening, für welche die mechanischen Gleichungen gelten, auch der gleichen einktrodynamischen und optischen Gestetze geltes, wie dies für die Größen erster Ordnung bereits erwissen ist. Wir vollen diese Vernutung (deren Inhalt im folgenden "Prinzip der Baltritätt" genannt werden wird) zur Vornutestening ebeen und auferenden die mit ihm ure schehnken wurvertegliche

ON THE ELECTRODYNAMICS OF MOVING BODIES

BY A. EINSTEIN

June 30, 1905

It is known that Maxwell's electrodynamics—as usually understood at the present time-when applied to moving bodies, leads to asymmetries which do not appear to be inherent in the phenomena. Take, for example, the reciprocal electrodynamic action of a magnet and a conductor. The observable phenomenon here depends only on the relative motion of the conductor and the magnet, whereas the customary view draws a sharp distinction between the two cases in which either the one or the other of these bodies is in motion. For if the magnet is in motion and the conductor at rest, there arises in the neighbourhood of the magnet an electric field with a certain definite energy, producing a current at the places where parts of the conductor are situated. But if the magnet is stationary and the conductor in motion, no electric field arises in the neighbourhood of the magnet. In the conductor, however, we find an electromotive force, to which in itself there is no corresponding energy, but which gives rise-assuming equality of relative motion in the two cases discussed-to electric currents of the same path and intensity as those produced by the electric forces in the former case.

Examples of this sort, together with the unsuccessful attempts to discover any motion of the earth relatively to the "light medium," suggest that the phenomena of electrodynamics as well as of mechanics possess no properties corresponding to the idea of absolute rest. They suggest rather that, as has already been shown to the first order of small quantities, the same laws of electrodynamics and optics will be valid for all frames of reference for which the equations of mechanics hold good.¹ We will raise this conjecture (the purport of which will hereafter be called the "Principle of Relativity") to the status of a postulate, and also introduce another postulate, which is only apparently irreconcilable with a definite velocity c which is independent of the state of motion of the emitting body. These two postulates suffice for the attainment of a simple and consistent theory of the electrodynamics of moving bodies based on Maxwell's theory for stationary bodies. Denoting by ∇ the EUCLID connection in spatial slices and assuming that the observer measures 1) a magnetic potential independent of time,

 $\mathcal{L}_{\mathsf{Z}}^{\mathcal{S}}\,\omega_{\mathsf{B}}^{1}=\mathbf{0}$

2) a spatially constant scalar electric potential,

 $d_{\mathcal{S}}\, \boldsymbol{\omega}_{\mathsf{E}}^{0} = \mathbf{0}$

3) a spatially constant magnetic vortex field,

 $abla \omega_{\mathsf{B}}^2 = \mathbf{0}$

the formula for the electric field may be evaluated to get

$$-\boldsymbol{\omega}_{\mathsf{E}}^{1} = (d_{\mathcal{S}} \,\boldsymbol{\omega}_{\mathsf{B}}^{1}) \cdot \boldsymbol{\mathsf{v}} + d_{\mathcal{S}} \, (\boldsymbol{\omega}_{\mathsf{B}}^{1} \cdot \boldsymbol{\mathsf{v}}) = \boldsymbol{\omega}_{\mathsf{B}}^{2} \cdot \boldsymbol{\mathsf{v}} - \frac{1}{2} \, \boldsymbol{\omega}_{\mathsf{B}}^{2} \cdot \boldsymbol{\mathsf{v}} = \frac{1}{2} \, \boldsymbol{\omega}_{\mathsf{B}}^{2} \cdot \boldsymbol{\mathsf{v}} \,,$$

or in terms of vector fields $\mathbf{E} = \frac{1}{2} \mathbf{v} \times \mathbf{B}$ which is just one-half of what is improperly called the LORENTZ force.
